

**Documentation for
Sample Size for a Cross-Sectional, Cohort, or Clinical Trial Studies**

Kevin M. Sullivan, PhD, MPH, MHA: edckms@sph.emory.edu
 Minn M. Soe, MD, MPH, MCTM: msoe@sph.emory.edu

This module calculates sample size for a cross-sectional study, a cohort study, or a clinical trial. The data input screen is as follows:

| Sample Size for Cross-Sectional & Cohort Studies | | |
|---|--|--------------------------|
| <input type="button" value="Calculate"/> | Two-sided confidence level(%) | 95 |
| <input type="button" value="Clear"/> | Power (1-beta or % chance of detecting) | 80 |
| | Ratio of Unexposed to Exposed in sample | 1.0 |
| | Percent of Unexposed with Outcome | 5 |
| Please fill in 1 of the following. The others will be calculated. | | |
| Odds ratio | | |
| Percent of Exposed with Outcome | | Between 0.0 and 99.9 |
| Risk/Prevalence Ratio | | |
| Risk/Prevalence difference | | Between -99.99 and 99.99 |

The four values required for a sample size calculation are:

- **Two-sided confidence level** – most individuals would choose a 95% confidence interval, but a different confidence interval could be entered.
- **Power** – most individuals choose a power value of 80% or 90%, however, any power level can be entered.
- **Ratio of Unexposed to Exposed in sample** – place the desired ratio of unexposed individuals to exposed individuals. If there are to be an equal number of unexposed and exposed, then enter the value of 1.0; if there are to be twice as many unexposed as exposed, enter the value of 2.0. Any other ratio can be entered.
- **Percent of Unexposed with Outcome** – enter an estimate of the percentage of unexposed individuals that will develop (or have) the outcome of interest. For example, in a randomized control trial, you would estimate the percentage of those in the comparison group that will develop the outcome of interest during the trial. In a cohort study, enter the percentage of unexposed individuals who will develop the outcome of interest during the study. In a cross-sectional study, enter the estimated prevalence of disease among the unexposed.

The user has the choice of entering an odds ratio **or** the percent of exposed with the outcome of interest or the risk (prevalence) ratio or the risk (prevalence) difference - just enter one of these. The results using the default values for a risk ratio of 2 are below:

Sample Size for Cross-Sectional & Cohort Studies & Clinical Trials

| | |
|--|-----|
| Two-sided significance level(1-alpha): | 95 |
| Power(1-beta, % chance of detecting): | 80 |
| Ratio of sample size, Unexposed/Exposed: | 1 |
| Percent of Unexposed with Outcome: | 5 |
| Percent of Exposed with Outcome: | 10 |
| Odds Ratio: | 2.1 |
| Risk/Prevalence Ratio: | 2 |
| Risk/Prevalence difference: | 5 |

| | Kelsey | Fleiss | Fleiss with CC |
|-------------------------|--------|--------|----------------|
| Sample Size - Exposed | 437 | 436 | 475 |
| Sample Size- Nonexposed | 437 | 436 | 475 |
| Total sample size: | 874 | 872 | 950 |

 Fleiss, Statistical Methods for Rates and Proportions, formulas 3.18 &3.19

CC = continuity correction

The sample size formula for the method described in Kelsey et. al. is:

$$n_1 = \frac{(Z_{\alpha/2} + Z_{1-\beta})^2 \bar{p}\bar{q}(r+1)}{r(p_1 - p_2)^2}$$

and

$$n_2 = r n_1$$

where

n_1 = number of exposed

n_2 = number of unexposed

$Z_{\alpha/2}$ = standard normal deviate for two-tailed test based on alpha level (relates to the confidence interval level)

Z_{β} = standard normal deviate for one-tailed test based on beta level (relates to the power level)

r = ratio of unexposed to exposed

p_1 = proportion of exposed with disease and $q_1 = 1-p_1$

p_2 = proportion of unexposed with disease and $q_2 = 1-p_2$

$$\bar{p} = \frac{p_1 + r p_2}{r + 1} \text{ and } \bar{q} = 1 - \bar{p}$$

The sample size formula *without* the correction factor by Fleiss is:

$$n_1 = \frac{[Z_{\alpha/2} \sqrt{(r+1)pq} + Z_{1-\beta} \sqrt{p_1 q_1 + p_2 q_2}]^2}{r(p_1 - p_2)^2}$$

$$n_2 = r n_1$$

For the Fleiss method *with* the correction factor, take the sample size from the uncorrected sample size formula and place into the following formula:

$$n_{uc} = \frac{n_1}{4} \left[1 + \sqrt{1 + \frac{2(r+1)}{n_1 r |p_2 - p_1|}} \right]$$

$$n_{ur} = r n_{uc}$$

When the input is provided as an odds ratio (OR) rather than the proportion of exposed with disease, the proportion of exposed with disease is calculated as:

$$p_1 = \frac{p_2 OR}{1 + p_2 (OR - 1)}$$

When the input is provided as a risk (or prevalence) ratio (RR) rather than the proportion of exposed with disease, the proportion of exposed with disease is calculated as:

$$p_1 = p_2 RR$$

When the input is provided as a risk (or prevalence) difference (RD) rather than the proportion of exposed with disease, the proportion of exposed with disease is calculated as:

$$p_1 = RD + p_2$$
